Preface

The *AIX Inspector Library* is a guide to the ordinary phrases (known as Inspectors) of the **BigFix Relevance Language**™ for AIX. With this manual and the ***Authoring Fixlet messages*** guide, you will be able to write **Fixlet**® messages and post them to **Fixlet Sites**.

Audience

This guide is for IT managers, product support groups and other people who want to write Fixlet messages for AIX computers. IT managers, in particular, will use the BigFix Enterprise Suite (BES) to keep a network of computers up to date and running smoothly without interruption.

Organization of this manual

For each Inspector in this library, there is a list of corresponding properties. The Inspectors are organized by category as follows:

- **Primitive Objects.** This chapter covers the basic data types supported by the language and describes the operations that can be applied to them.
- **World Objects.** This chapter covers the keywords used to create all the 'top' level objects of the world. The properties of these objects provide access to all levels of the machine state that can be inspected.
- **File System Objects.** This chapter covers the keywords for extracting information from the file system, like files, drives, pathnames, folders, etc. It also includes the keywords needed to identify and compare version information of files.
- **System Objects.** This chapter covers the keywords available for querying the name and version of the operating system. This chapter also covers the keywords used to describe the vendors and types of the various processors that coexist in a typical computer system.
- **Site Objects.** This chapter covers the keywords that query the properties of Fixlet sites to which the client is subscribed.
- **Client Objects.** This chapter covers properties of the client application hosting the relevance evaluation.

- **Environment Objects.** Environment objects are provided to access environment variables. These are the same variables you're used to seeing in a shell like BASH when you type the 'printenv' command. Note that you're inspecting the environment of the application executing the relevance clause, which may or may not match the environment of other applications on the computer.
- **User Objects.** This chapter covers the local and current user keywords. A Local User object is provided to access the user data of the local machine. Note that domain users are not available through this inspector.
- **Action Objects.** These are the keywords associated with properties available for inspection during the execution of BigFix Actions.
- **Networking Objects.** These are the keywords used to query the local network configuration.
- **Introspectors.** These are objects that talk about the language itself, letting you interrogate the types and objects of the relevance language.
- **Key Phrases (Inspectors).** This chapter provides an alphabetical list of all the Inspector key phrases along with the form, context object type, and resulting object type.

Conventions Used in this manual

This document makes use of the following conventions and nomenclature:

Convention	Use
Bold Sans	A bold sans-serif font is used for Inspector headers.
`Mono-space`	A mono-spaced font is used to indicate expressions in the Relevance Language.
{curly braces}	Braces are used to indicate the comparison {=, !=}or arithmetic operators {+, -} that are available for a binary operation.
<angle bracket>	Angle brackets are used to indicate an object type. For instance to indicate the creation and usage of a particular object, you might see “absolute value of <integer>” which indicates that an integer is to follow the “absolute value of” keyphrase.
Italics	An Inspector form. Some Inspectors are simple keywords. Others are a keyword in combination with another Inspector. Still other forms allow iteration through object lists. Each form is defined below
Small print	The small print beneath the description of each Inspector lists the first implementation for every relevant operating system.

Examples

Square bullets and a mono-spaced font denote examples of Inspectors as used in a Relevance Expression. If you have a color version of this file, these square bullets are also red:

- `concatenation of "light" & "year"`
  - Returns "lightyear"

Versions

Most Inspectors have equivalent implementations on other operating systems, allowing you to write cross-platform relevance expressions. There are exceptions, of course. To keep track of them for each Inspector and operating system, the debut BigFix version is listed at the end of the description, e.g.:

```
Win:1.2, Lin:3.1, Sol:3.1, HPUX:4.0, AIX:4.1
```

These are the abbreviations for some of the current operating systems:

Win: the Windows version of the BigFix Enterprise Suite (BES).

Lin: the SUSE and Red Hat Linux versions of BES.

Sol: the SUN Solaris operating system version of BES.

HPUX: the Hewlett-Packard Unix version of BES.

AIX: the AIX version of BES.

Mac: the Macintosh version of BES.

Introduction

This manual details the properties and operators of the BigFix Inspector keywords. Inspectors are the basis of the Relevance Language. They can be thought of as object-oriented representations of the underlying computer system. With Inspectors, you can write Relevance expressions that query all aspects of the computer. Inspectors are also used to produce substituted variables in BigFix Actions. They can also be used to create human-readable descriptions of any given computer system.

You will notice that many of the keywords of the language are not unique; they get their meaning from their context. Accordingly, their definitions often include a phrase to define the context of each Inspector, such as "character of <string>" or "character <integer> of <string>."

This document describes inspectors for the AIX Operating System. Contact your BigFix sales representative for information about Inspector Guides for other operating systems, including Windows, Solaris, HP, Red Hat and Mac.

In the following pages, you will find tables defining the inspectors of the relevance language. The inspectors come in several **forms** depending upon their context:

Form	Syntax required
Cast	<object> as keyword
Global	keyword
Index	keyword *index* of <object>
Named	keyword "*name*" of <object>
NamedGlobal	keyword "*name*"
Numbered	keyword *number* of <object>
NumberedGlobal	keyword *number*
Plain	keyword of <object>

These differ from one another in format and in the syntax they require. Except for Cast, these forms can be used to access both single objects and *lists* of objects by using the plural form of the keyword. The plurals are listed in the Keyword section later in this document.

Creation Methods are used to create objects of the specified type, and various **Properties** are available for each object.

Operators list the binary and unary operations that can be performed with the given object type. Binary operators take two inputs and generate one output. The integer '+' (addition) operator is an example of a binary operation. Unary operators take a single input and generate a single output. The boolean 'Not' operation is an example of a unary operation.

Primitive Objects

The relevance language is based upon a comprehensive set of primitive objects. These primitives are the basic building blocks of the more complex objects to follow.

Boolean

Creation Methods

These boolean creation methods are in addition to the other properties that return the boolean type.

Key Phrase	*Form*	Description
<string> as boolean	*Cast*	Returns a boolean TRUE or FALSE from a string. The string must contain values of "TRUE" or "FALSE". Case is ignored. For example, "FalSe" as boolean = FALSE. Win:1.2, Lin:3.1, Sol:3.1, HPUX:4.0, AIX:4.1, Mac:4.1
bit <integer> of <integer>	*Numbered*	Return TRUE if the bit referenced by the integer is on. Bits are numbered starting with zero being the least significant. For example, bit 0 of 5 and bit 2 of 5 and not bit 1 of 5 = TRUE. Win:1.2, Lin:3.1, Sol:3.1, HPUX:4.0, AIX:4.1, Mac:4.1

String

A string literal is written within double quotes. Special characters must be inserted by using the percent sign followed by 2 hex digits. Special characters include those characters with ASCII codes less than the 'space' character (hex 20) or greater than 'tilde' character (hex 7f) as well as the percent character itself (25 hex). For example, to create a string containing a null character and a percent character use "a null is %00, the percent itself is %25". Conversion to upper and lower case is also provided. String works in combination with the string position and substring data types. A string position is a point within a string. It can be compared to an integer, but it also acts as a pointer within a string so that the preceding and following text can be extracted. A substring is a part of a larger string. All operations allowed on a string can be performed on a substring. There are two substrings "be" in the string "To be or not to be". The substrings only differ in their positions within the string.

Creation Methods

These string creation methods are in addition to the other properties that return the string type.

Key Phrase	*Form*	Description
wake on lan subnet cidr string	*PlainGlobal*	Returns the subnet the client is in for Wake on Lan (WoL) purposes. The client sends information to the relay during registration that is used to decide which subnet the client is in. The relay returns the subnet to the client, which is the value this Inspector exposes. This value is used to send WoL commands to forwarders. To wake a machine by computer ID, the server looks up the mac address and subnet of that machine. It then tries to identify clients that have been configured as WoL forwarders within the same subnet and routes WoL commands to those forwarders, sending them the mac address of the machine that needs to be awoken. Note

Many Inspectors return string values from the operating system using a variety of APIs. For the most part, these strings are encoded as single-byte character sets (SBCSs) or multi-byte character sets (MBCSs) depending on the active code page. You can use the code page Inspectors to determine which page is currently active on the client.

Examples

- `255 as hexadecimal`
  - Returns the string "ff".

  - Returns TRUE.

String Position

String position works in combination with the string and substring data types. A string position is a point within a string. It can be compared to an integer (which it is derived from), but it also acts as a pointer within a string so that the preceding and following text can be extracted. A substring (a part of a larger string) is derived from a string object.

Creation Methods

Key Phrase	*Form*	Description
end of <substring>	*Plain*	Creates an object corresponding to the position in the string of the end of the substring. For example, end of first "be" of "To be or not to be" = 5. Win:1.2, Lin:3.1, Sol:3.1, HPUX:4.0, AIX:4.1, Mac:4.1
position <integer> of <string>	*Numbered*	Creates an index (zero based) into the string. For example, position 5 of "to be or not to be" = 5. Win:1.2, Lin:3.1, Sol:3.1, HPUX:4.0, AIX:4.1, Mac:4.1

Key Phrase	*Form*	Description

Rope

The rope object is a way to efficiently concatenate long strings. String literals in the Relevence language are limited to 512 characters, but internally, they can be any length. Note

The string format for a time object is given by the MIME standard. When output as a string, the format used is:
ddd, DD mmm YYYY HH:MM:SS sZZZZ
where:

ddd	The day of the week. Abbreviations are Mon, Tue, Wed, Thu, Fri, Sat, Sun.
DD	The day of the month. A leading zero will be applied to make it two characters wide.
mmm	The Month. Abbreviations are Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov, Dec.
YYYY	The year.
HH	The hour of the day. It is always output at two digits. Possible values run from 0 to 23. The digits 00 are used to designate midnight.
MM	The minutes of the hour. It is always output as two digits. Possible values run from 0 to 59.
SS	The seconds of the minute.
s	A single character representing whether the time is east or west of Greenwich. The value of + means east of Greenwich while the value - means west of Greenwich.
ZZZZ	The number of minutes east or west of Greenwich.

To create a string from a literal, use the format:**ddd,DD mmm YYYY HH:MM:SS zoneinfo**
where:

ddd	The optional day of the week. Abbreviations are Mon, Tue, Wed, Thu, Fri, Sat, Sun. Case is not important in these names. If provided it must be correct. For example, time "Sat, 19 jun 1998 00:00:00 +0000" will fail since June 19, 1998 was a Friday.
DD	The day of the month. One or two digits are allowed.
mmm	The Month. Abbreviations are Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov, Dec. Case is not important.
YYYY	The year. A two, three or four digit year. If two digits are given a base of 1900 is assumed.
HH	The hour of the day. It is always input at two digits. Possible values run from 0 to 23. The digits 00 are used to designate midnight.
MM	The minutes of the hour. It is always output as two digits. Possible values run from 0 to 59.
SS	The seconds of the minute. Range from 0 to 59. This is optional. If seconds are not present, the preceding colon should also not be present
Zoneinfo	The time zone information. It is provided in one of these formats: Single character + or - followed by 4 digits. The 4 digits are interpreted as HHMM two digits of hours and two digits of minutes. Plus designates east of universal time while minus designates west of universal time. Three letters for the civilian name of the time zone. cdt, edt, mdt, pdt are the designations for central, eastern, mountain and pacific daylight savings time while cst, est, mst, pst are the designations for central, eastern, mountain and pacific standard time. gmt designates Greenwich mean time. A single letter military name of the time zone. Military time zones use single letters from a to z, excepting j. a-m represent offsets from universal time of -1 to -12 hours respectively. z represents 0 offset.

File

For each file in the file system, you can create a corresponding file object and inspect its properties. Inspectors are also provided to look at version data of executable files. File objects are derived from filesystem objects.

Creation Methods

See application objects for additional creation methods

Key Phrase	*Form*	Description
<symlink> as file	*Cast*	Converts a symlink object into the file it points to. Lin:7.0, Sol:7.0, HPUX:7.0, AIX:7.0
default web browser	*PlainGlobal*	Creates an object corresponding to the default web browser. Note

File systems that do not maintain the creation or last accessed times will often return the last modification time when queried for the creation or last accessed times or files. Modification times are preserved when files are copied. Thus, it is not uncommon to see a file that appears to have been modified before it was created.

Folder and file names may be case sensitive. Use “as uppercase” or “as lowercase” if you don’t know the actual case when making comparisons. Iterating through folders with many files can be time consuming.

Note

The format of the string returned when casting a file using 'as string' is:
"<fileName>" "<version>" "<fileDesc>" "<fileVersion>" "<companyName>"
Where:

<fileName>	The name of the file
<version>	The 'Product Version' of the file.
<fileDesc>	The value 'FileDescription' of version block 1 of the file.
<fileVersion>	The value 'FileVersion' of version block 1 of the file.

  - Returns TRUE if there are 3 files matching the wildcard pattern siteico*.bmp.

- `names of find files "*.exe" of windows folder`
  - Returns a list of the names of all the executable programs in the Windows folder.

- `modification time of masthead of current site < time "4 Aug 1997 01:00 pdt"`
  - TRUE if the masthead is older than the specified date.

- `lines of file "c:\autoexec.bat"`
  - Returns all the lines in the specified autoexec.bat file.

Application

Application objects derive from file objects. Therefore, application objects inherit all of the properties of the file object. This means that you can inspect properties such as 'modification time' or 'Product Version' of an application just as you would a file. See the properties of a file object for a complete list of these. The real power and primary purpose of the application object is their creation. The creation methods are optimized in anticipation of the importance of this object.

Creation Methods

Key Phrase	*Form*	Description
application <string>	*NamedGlobal*	Creates an application object for the name provided. Win:1.2, Lin:6.0, Sol:6.0, HPUX:6.0, AIX:6.0
application <string> of <folder>	*Named*	As with the file object, you can create an application object by naming it relative to its parent folder. Win:1.2, Lin:6.0, Sol:6.0, HPUX:6.0, AIX:6.0

Note

See ‘File’ for a list of the Application properties. Folder and file names may be case sensitive. Use “as uppercase” or “as lowercase” if you don’t know the actual case when making comparisons. For Windows versions of these Inspectors, a properly installed application will register itself with the operating system. It does this by creating a registry sub-key usually named after the executable. The regapp Inspector uses the default value of this sub-key as a string that is the full pathname of the executable.

Examples

- `exists application "notepad.exe" of the windows folder`

Using the application of folder creation method, this example locates the notepad application provided it exists in the Windows folder.

Folder

For every folder that exists in the file system, you can create a folder object. The properties of this object allow you to examine many aspects of the system. Folder objects are derived from filesystem objects. On the Macintosh, there are dozens of specialized folders; access to them depends on the domain. If the domain is not specified, it defaults to the system domain.

Although that returns links along with the files, it doesn't return broken links. Lin:7.0, Sol:7.0, HPUX:7.0, AIX:7.0

Note

Folder and file names may be case sensitive. Use “as uppercase” or “as lowercase” if you don’t know the actual case when making comparisons. Be careful not to iterate through folders that contain a large number of files. Counting files in such a folder can be slow. Always try to use the most efficient techniques to minimize the client overhead. Consider using the “find file” Inspector which allows you to filter sets of files by using the wildcard.

Examples

- `mode of folder "/tmp" = "rwxrwxrwt"`
- Returns TRUE if all permissions are granted for the specified folder.

File Section

Many programs and utilities store their settings in 'ini' files. This object is designed to access these settings. An 'ini' file is composed of zero or more named sections, each with zero or more keys. Each key is identified by name and has a string value.

Creation Methods

Key Phrase	*Form*	Description
section <string> of <file>	*Named*	Creates a file section for the name given. A case-insensitive search is performed to locate the named section in the file. Searching through files for configuration data can be a slow process. Particularly for large ini files. In this case you may want to find another method that requires less computation. Win:1.2, Lin:3.1, Sol:3.1, HPUX:4.0, AIX:4.1, Mac:6.0

Properties

Key Phrase	*Form*	Return Type	Description
key <string> of <file section>	*Named*	<string>	Returns a string containing the value for the name provided. A case-insensitive search is performed through the section of the file. Win:1.2, Lin:3.1, Sol:3.1, HPUX:4.0, AIX:4.1, Mac:6.0

Note

Files with an extension of .ini are common in Windows systems, but rare in unix systems. However they are a handy cross-platform way of maintaining a collection of named variables.

File Content

Content objects can be constructed from file objects to inspect their contents.

Creation Methods

Note

See "file section" for a more detailed inspection of .ini files.

Examples

  - Returns TRUE if the exact character sequence "Dell" is located in the file.

- `content of file "oeminfo.ini" of system folder as lowercase contains "emachines"`
  - Returns TRUE if either of the strings "emachines" or "eMachines" is found in the file.

Key phrase	Return Type	Description
<version> {cmp} <version>	<*boolean*>	Returns a boolean TRUE or FALSE, depending on the comparison operator, where: • {cmp} is one of: =, !=, <, <=, >, >= . Win:1.2, Lin:3.1, Sol:3.1, HPUX:4.0, AIX:4.1, Mac:4.1

Note

Using the numeric version data is better than identifying an application based on version block strings. If you know the numeric version information and that the developer has identified each release of his application uniquely, then this is the way to proceed. It requires far less overhead than the other method. Furthermore, if you know that the numeric version data is monotonically increasing then you can compare their values using the special comparison operators.

Examples

- `"MyApp 1.2" as version = "MyApp 1.2" as version`

  On unix, the version object contains a string. The comparison is expecting the string parts to match. If one of the operands comes from a property of some other object, this provides a way to compare a version against that property, provided they match in the rest of the string.

- `version of client as string`

  Returns a string like "4.0.3.7".

- `extrema of (version "1.1"; version "2.3"; version "0.9")`

  Returns the minimum and maximum values of the set: 0.9, 2.3.

Application Usage Summary

To enable these Inspectors, you first need to create the client setting _BESClient_UsageManager_EnableAppUsageSummary and initialize it to 1. You can also limit the summary to a subset of applications by creating _BESClient_UsageManager_EnableAppUsageSummaryApps and initializing it to a list of apps to include (or exclude). The value of this setting should look like +:app1:app2:app3: to add apps to the scope, and -:app1:app2: to exclude apps. The case is ignored. For instance, to enable summaries on the Word application, use the value +:winword.exe:.

Symlink

Inspectors can analyze the file objects (files and folders) that symlinks point to by using the standard file Inspectors. The symlink Inspectors, on the other hand, allow you to analyze the properties of a symlink itself, not just the underlying file. There are many properties that symlinks have in common with files, such as name, pathname, parent folder, etc. In addition, a symlink has a value corresponding to the file object it points to. You can also determine if the file is available or not.

Logical Volume Manager

On AIX, the logical volume manager provides a flexible means of allocating disk space using volume groups, logical volumes, and physical volumes. A volume group is a collection of one or more physical volumes and a logical volume is an abstraction representing a pool of disk space. The disk space assigned to a logical volume appears contiguous to the user, but it may actually be distributed across one or more physical volumes within a single volume group.

Creation Methods

Key Phrase	*Form*	Description
logical volume manager	*PlainGlobal*	Returns the global logical volume manager on AIX systems. AIX:7.0

Properties

Key Phrase	*Form*	Return Type	Description
volume group <string> of <logical volume manager>	*Named*	<volume group>	On an AIX system, returns a volume group from the logical group whose name property matches the given string. AIX:7.0
volume group of <logical volume manager>	*Plain*	<volume group>	Returns the volume group corresponding to the given logical volume manager. AIX:7.0

Examples

- `number of volume groups of logical volume manager`

Returns the number of volume groups in the global logical volume manager.

Logical Volume

A logical volume consists of an array of identically sized logical partitions. The partition size of a logical volume is determined by the volume group that contains it, and is the same as the volume group's physical partition size. Contiguous logical partitions within a logical volume may map to discontiguous physical partitions, possibly distributed across multiple physical volumes. A logical volume may be configured so that its logical partitions are mirrored to protect data from hardware failures. Mirroring may be configured so that each logical partition maps to either 2 or 3 physical partition mirrors.

Creation Methods

Key Phrase	*Form*	Description
logical volume <string> of <volume group>	*Named*	Returns a logical volume within the specified volume group whose "name" property matches the given string. AIX:7.0
logical volume of <filesystem>	*Plain*	On an AIX system, returns the logical volume corresponding to the given filesystem. AIX:7.0

<logical volume> as string	*Cast*	<string>	Casts an AIX logical volume as a string type. AIX:7.0
label of <logical volume>	*Plain*	<string>	Returns the label of the specified logical volume. If the logical volume contains a filesystem, then then this will be the full pathname of the mount point of the file system, eg. "/home". AIX:7.0
maximum partition count of <logical volume>	*Plain*	<integer>	Returns the maximum number of logical partitions that the specified logical volume contains. A system administrator may set this value to prevent a logical volume from growing beyond a given size. AIX:7.0

Key Phrase	*Form*	Return Type	Description
minor number of <logical volume>	*Plain*	<integer>	Returns the minor number of the specified volume group. Each logical volume is represented by a device special file (located in directory /etc). The major number of the device special file is associated with the volume group containing the logical volume, and the minor number of the device special file is associated with the logical volume. AIX:7.0
mirror count of <logical volume>	*Plain*	<integer>	Returns the number of mirrors that the logical volume has (a value between 1 and 3). AIX:7.0

partition count of <logical volume>	*Plain*	<integer>	Returns the number of partitions in the specified logical volume. If mirroring is not enabled for the logical volume, then each logical partition maps to a physical partition within the logical volume's volume group. If the logical volume is mirrored, then each logical partition maps to multiple physical partitions within the logical volume group. In this case, the total number of physical partitions occupied by the logical volume will be the product of the partition count and the mirror count. AIX:7.0
volume group of <logical volume>	*Plain*	<volume group>	Returns the volume group that contains the given logical volume. AIX:7.0

- `partition count of logical volume "splat" of volume group "dave" of logical volume manager`
  - Returns the number of partitions existing on the specified logical volume.

Volume Group

On AIX systems, physical disk volumes are organized into volume groups. The partition size of a physical volume is determined by the volume group that it belongs to. If multiple physical volumes belong to the same volume group, then they must all have the same partition size. A typical partition size might be 16 or 32 megabytes.
